1.0 Introduction

A study has been conducted to determine the earliest abort once around (AOA) time for the first orbital flight test (OFT-1) mission. The study uses latest estimates of vehicle weights and propulsion for OFT-1. Trade analyses to indicate variations in AOA time for shuttle subsystem changes (such as orbital maneuvering system (OMS) or reaction control system (RCS) propellant loadings) are included in this paper. In addition, the effects of first stage attitude steering as a function of relative velocity for a nominal profile are presented. Data are presented to indicate the effect of designing first stage steering for earliest AOA time and then having engine out at times after the design point.

2.0 Groundrules and Constraints

This earliest AOA analysis is for OFT-1. Vehicle weights used in the analysis are indicated in Tables I through III. Data are presented in the tables for nominal and AOA profiles. Table I contains weight evaluations for dry weights, propellant residuals, reserve propellants, and for the solid rocket booster (SRB). Tables II and III contain main propulsion system (MPS) propellant weights and OMS and RCS weights, respectively. Some of the significant groundrules and constraints used in this analysis are:

- a. three-degree-of-freedom flight (3 DOF) is simulated.
- b. no loads or maximum dynamic pressure limits are imposed

on the trajectory simulations

- c. launch from KSC
- d. payload is 10000 pounds
- e. orbit inclination is 38. degrees, launch azimuth of approximately 62. degrees
- f. the 270-75 solid rocket motors (SRM) are used (Table IV)
- g. 100% space shuttle main engine (SSME) thrust from liftoff to AOA
- h. SSME throttled to 109% thrust following main engine out (AOA)
- i. OMS and RCS are not required for nominal flight to main engine cutoff (MECO)
- j. OMS and RCS ignition at SRB separation in AOA simulations
- k. MECO targets are
 - 60. NMI Altitude
 - 0.5 DEG Flight-Path Angle
 - 25668. FT/SEC Inertial Velocityfor both nominal and AOA
- l. OMS and RCS propellant post MECO for AOA are:
 - OMS 6276 LB (approximately 280 FT/SEC)
 - RCS 5780 LB
- m. nominal profile is optimized for earliest AOA
- n. maximum acceleration limit is 3 g's

The Space Vehicle Dynamics Simulation (SVDS) Program is the simulation tool used in this study. The 3-DOF simulation mode of the program is used with no winds or yaw biasing being simulated. Co-planar flight is simulated from liftoff to MECO.

3.0 Earliest AOA Analysis

In order to determine the earliest AOA time for the shuttle vehicle as configured in this study, first stage steering (including the pitch over maneuver) is optimized for various engine out times. The earliest engine out time for which the given MECO conditions can be achieved is defined as the earliest AOA time.

First stage steering for the AOA is simulated by

- a. vertical flight to tower clearance
- b. vehicle pitch over at a constant body rate for 10.0 seconds
- c. zero angle of attack flight from time of pitch over termination to SRB separation

Figure 1 contains SSME propellant at MECO for various engine out times and pitch over rates. The data constitutes an optimization of pitch over rate for each of the engine out times and indicates that the earliest engine out time for which MECO conditions can be achieved is approximately 24. seconds from liftoff. Examination of the optimum pitch over rate data indicates a rate of change of .003 DEG/SEC/SEC of AOA time.

Parametric trajectory data for the simulation cases of Figure 1 are presented in Figures 2 through 5. Figures 2 through 4 contain SRB staging data (staging altitude, inertial velocity, and inertial flight-path angle, respectively) as a function of pitch over rate and engine out time. Figure 5 contains down range position at MECO. The data are for an AOA profile and

evaluations of the parameters at the optimum pitch over rates are indicated for each engine out time. Data of Figure 2 indicate that SRB staging altitude changes at the rate of .23 K-FT/SEC of AOA time when the pitch over maneuver is optimized for the engine out. Figure 6 contains range at MECO and staging altitude as a function of engine out time. The data are based on optimum pitch over rate for each engine out time.

4.0 Earliest AOA Variation For Subsystem Changes

Figure 7 contains data indicating SSME propellant at MECO as a function of engine out time. The data indicate that the rate of change of SSME propellant at MECO to AOA time variations is 250 LB/SEC. That is, 250 pounds of SSME propellant (at MECO) is required to change the AOA time by 1. second. Based upon the current estimate of OFT-1 weights and propulsion, earliest AOA time is 24.4 seconds. This implies SSME propellant depletion at MECO of the AOA profile. An additional 6100 pounds of SSME propellant at MECO ($250 \text{ LB/SEC} \times 24.4 \text{ SEC}$) is required to reduce earliest AOA to liftoff. This 6100 pounds of SSME propellant at MECO is equivalent to a 6600 pound reduction in payload ($1.08 \text{ LB Payload/LB SSME prop} \times 6100 \text{ LB}$). AOA capability off the pad is available for a payload of 3400 pounds ($10000 - 6600$) for current OFT-1 weight and propulsion data. One control element which may be used to provide earlier AOA capability while keeping the payload fixed (at 10000 pounds) is to vary the OHS and RCS loadings. This may be done in

either of two ways:

- a. reduction of the total OMS and RCS loading with reduction in the post-MECO propellant requirement
- b. fixed OMS and RCS loading with more propellant allotted for pre-MECO burn

Consider AOA time capability variation by method (a). A 1000-pound OMS and RCS off loading (with 1000 LB post-MECO requirement reduction) results in an increase of 926 pounds of SSME propellant at MECO. This is equivalent to a 3.7 second reduction in earliest AOA time.

Using method (b) as a control element with fixed OMS and RCS loadings, allowing 1000 pounds more propellant to be burned pre-MECO results in 1130 pounds of SSME propellant at MECO. This is equivalent to a 4.52 second reduction in earliest AOA time.

It should be noted that extremely large variations in the OMS and RCS loadings are required if this would be the only element employed to reduce earliest AOA time from its present value to liftoff.

5.0 Nominal Profile

As part of this analysis, a nominal profile was developed. The first stage steering profile for the nominal trajectory is the attitude/relative velocity history of the AOA trajectory. This results in a lofted profile for the nominal trajectory. Figure 8 illustrates the altitude histories for the nominal and AOA profiles. One result of the lofted nominal trajectory

is a reduction in maximum dynamic pressure. Figure 9 contains dynamic pressure histories for the nominal and AOA trajectories. Tables V and VI contain trajectory data for the two boost profiles. Table V contains data for the time of maximum dynamic pressure and Table VI contains data for MECO. The targeted guidance cutoff conditions are also included in Table VI. Data of Table V indicate a 600 ft/sec variation in staging velocity between the nominal and AOA profiles. Since first stage steering for the nominal trajectory is derived from the AOA profile, nominal steering commands for the last 600 ft/sec velocity region had to be obtained. Figure 10 contains vehicle attitude commands as a function of relative velocity. Five candidate profiles are indicated to cover the velocity gap from AOA SRB separation to nominal SRB separation. The attitude profile numbered 5 in Figure 10 is selected for use in the nominal trajectory of this study. Selection of profile 5 is based on obtaining a continuous pitch over rate during the region in question. However, profile 5 does not provide maximum nominal performance. Figures 11 and 12 indicate the effects of using steering profiles 1 through 5. Profiles 1 through 4 are indicative of a pitch down maneuver. Since the nominal trajectory has been lofted by optimum AOA steering commands up to a velocity of 3600 ft/sec, a pitch down maneuver during the terminal phase of first stage flight increases vehicle performance. (See SSME propellant at MECO, Figure 11.) The data of Figures 11 and 12 indicate pitching

the vehicle down during the last portion of SRB flight has the following effects:

- a. increases performance
- b. decreases separation altitude and flight-path angle
- c. increases separation velocity and dynamic pressure
- d. decreases the initial guidance pitch command

Since the nominal profile in this study is not performance critical, no further investigation of the pitch down maneuver was conducted. This item may be pursued at a later date when the definition of acceptable SRB staging conditions are obtained.

6.0 Effects of Engine Out at Later Than Design Times

As previously stated, the profiles in this study are designed for the engine out case. The nominal trajectory uses first stage steering commands from the engine out (AOA) profile. Several trajectories were simulated to evaluate the effects of designing first stage steering for earliest AOA time and having the engine go out at a later time.

Figures 13 and 14 illustrate the effects of engine out after the design (earliest) point. Figure 13 indicates the variation in vehicle state at SRB separation as a function of engine out time. The first stage steering profile used in all the simulations is optimized for an engine out time of 24 seconds. Data are presented in the figure to indicate staging velocity, flight-path angle and altitude of the nominal trajectory, the nominal profile being the limiting case for delayed engine out (i.e.

time of delayed engine out is MECO time). Similarly, Figure 14 presents variations at MECO for engine out later than the earliest AOA time. The data indicate performance increases (SSME propellant at MECO) from the zero value for engine out at 24.4 seconds toward the nominal trajectory value. Range at MECO shows little variation for the engine out times of Figure 14.

7.0 Conclusions and Recommendations

The earliest AOA time for OFT-1 is 24.4 seconds as the vehicle is currently configured (10000 pound payload). Engine out off the pad capability has been reduced to a payload of approximately 3400 pounds. The increase in earliest AOA time and decrease in maximum payload for engine out on the pad are a result of updated evaluations of 1) aerodynamic predictions and vehicle weights and 2) a change in groundrules governing SSME operation. The trade factors for earliest AOA time as a function of SSME propellant at MECO and the parametric data of this report should provide a data base for predicting AOA time as updates are made in the OFT-1 vehicle.

It is recommended that the engine out and nominal profiles of this study be evaluated relative to load constraints. Throttling may be necessary to reduce maximum dynamic pressure in the nominal trajectory. The earliest AOA time may be effected by having to adhere to a constraint profile.

FIGURE 9 DYNAMIC PRESSURE HISTORY - NOMINAL AND AOA

TABLE V

**VEHICLE STATE AT
MAXIMUM DYNAMIC PRESSURE AND
SOLID ROCKET BOOSTER STAGING**

I. Maximum Dynamic Pressure

| | Nominal | AOA |
|---------------------------------------|---------|--------|
| Time - SEC | 56. | 56. |
| Altitude - FT | 33144. | 31769. |
| Inertial Velocity - FT/SEC | 2042. | 1959. |
| Inertial Flight-Path Angle - DEG | 34.30 | 33.03 |
| Dynamic Pressure - LB/FT ² | 596. | 532. |

II. SRB Staging

| | | |
|---------------------------------------|---------|---------|
| Time - SEC | 121.23 | 121.23 |
| Altitude - FT | 171046. | 156132. |
| Inertial Velocity - FT/SEC | 5153. | 4579. |
| Inertial Flight-Path Angle - DEG | 34.63 | 34.21 |
| Dynamic Pressure - LB/FT ² | 15. | 19. |
| Range - MI | 7.59 | 15.11 |

TABLE VI

VEHICLE STATE AT MAIN
ENGINE CUTOFF (MECO)

I. Trajectory
Cutoff
Conditions

| | |
|----------------------------|---------------|
| Altitude | 60. NMI |
| Inertial Flight-Path Angle | 0.5 DEG |
| Inertial Velocity | 25668. FT/SEC |

II. Vehicle MECO State

| | Nominal | AOA |
|----------------------------------|-----------|-----------|
| Time - SEC | 498.184 | 682.610 |
| Weight - LB | 315639. | 268733. |
| Inertial Velocity - FT/SEC | 25667.1 | 25667.6 |
| Inertial Flight-Path Angle - DEG | 0.506 | 0.502 |
| Inclination - DEG | 38.01 | 37.92 |
| Latitude - DEG | | |
| Geocentric | 33.2721 | 34.2679 |
| Geodetic | 33.4456 | 34.4439 |
| Longitude - DEG | -68.1931 | -64.7499 |
| Radius - FT | 21290308. | 21290308. |
| Inertial Azimuth - DEG | 70.4650 | 72.6569 |
| Range - NMI | 701.62 | 883.46 |
